

Problem Statement on Blinkit Orders

Ten business problems to analyze with SQL

Context

Blinkit is a quick-commerce company delivering groceries and daily essentials in minutes. Its order data (**blinkit_orders**, about 3.86 million orders from January 2022 to May 2026) records every order's timing, location, customer tier, payment, pricing, delivery performance and final status. Growing profitably in this market means making sound decisions on growth, operations, customers and pricing. The ten problem statements below frame the questions the data must help answer.

Problem Statements

01

BUSINESS GROWTH

Is the business growing consistently?

Leadership needs to know whether sales are growing and how fast. Monthly sales value (GMV), order volume and average order value must be tracked from 2022 to 2026, along with month-over-month and year-over-year growth, to spot slowdown months and seasonality and to set realistic growth targets.

02

REVENUE LEAKAGE

How much revenue is lost to failed orders, and why?

Orders that are cancelled, returned or only partly delivered bring in no revenue or reduced revenue. The business must quantify this loss and identify the reasons behind it, such as stock-outs, late delivery, wrong items or damaged products, so that the most costly causes are fixed first.

03

DELIVERY SPEED

Does delivery speed drive customer loyalty?

Quick commerce depends on fast delivery, but it is unclear how much speed really matters. It must be understood whether slower deliveries lead to lower ratings and fewer repeat orders, and at what delivery time satisfaction starts to fall, to decide how much to invest in dark-store capacity and rider supply.

04

PEAK DEMAND

When is demand highest?

Orders are not spread evenly across the week. Blinkit needs to identify the days and hours with the highest order volume and check whether delivery performance suffers at those times, so that riders, pickers and stock refills can be planned accurately.

05**LOCATION PERFORMANCE****Which cities and zones are stars, and which underperform?**

Blinkit operates in many cities and zones that differ in volume, basket value, delivery time and failure rate. It must identify the strongest and weakest locations to decide where to expand dark stores, where to fix operations and where to cut losses.

06**PROMOTIONS****Are promo codes worth their cost?**

Every promo code costs money in discounts. The company needs to assess whether each code increases basket size, attracts new customers and justifies its cost compared with orders placed without a promo, so it can decide which codes to scale, redesign or stop.

07**CUSTOMER VALUE****Who are the most valuable customers?**

Loyalty tiers (Bronze, Silver, Gold and Platinum) and cashback rewards are meant to create more valuable customers. It must be evaluated whether higher tiers deliver more orders and revenue per customer relative to the cashback they cost, so that the retention budget goes where it pays off.

08**RETENTION****Do new customers come back?**

Retention is the biggest driver of customer lifetime value. The business needs to measure what share of new customers place a second order within 30 days and how this varies by sign-up month, to find weak cohorts and time win-back offers well.

09**PAYMENTS AND PLATFORMS****Which payment methods and platforms carry the most risk?**

Payment methods and platforms (Android, iOS and Web) can differ in order value and in how often orders are cancelled or returned. Blinkit must find which combinations are riskiest and which are most valuable, to decide where to push incentives and where to reduce risk, for example with cash on delivery.

10**BASKET ECONOMICS****Are small baskets losing money?**

Small orders carry a high delivery cost compared with their value. The business must understand how basket size relates to delivery fees, tips and failure rates, to set the right minimum order value, free-delivery threshold and small-cart fees, and to design nudges that grow the basket.
